ABSTRACT

Pituranthos chloranthus, commonly known in Arabic as ‘Aljen’, is a small aromatic plant which grows spontaneously in North Africa and it is widespread in central and southern Tunisia. This paper is the first report of its kind on the isolation and characterization of certain coumarin derivatives from the extract of the roots and aerial parts of this plant. Background: Pituranthos chloranthus (Apiaceae) commonly known as ‘Aljen’ is an endemic Tunisian aromatic plant, largely used in folk medicine. This plant contains bioactive compounds, particularly coumarin derivatives. The objective of the present study was to isolate and characterize some bioactive phytochemical constituents from the extract of the aerial parts and roots of Pituranthos chloranthus. Methods: Different extracts were subjected to column chromatography and eluted with solvent mixtures of increasing polarity (petrol-ether, ethyl acetate and methanol) to isolate five pure Products. The structure of the isolated compound was established using spectroscopic methods (UV, 1H-NMR, 13C-NMR, DEPT, HMBC, HMQC, COSY), and HRMS. Results: Isoimperatorin, osthol and oxypeucedanin were isolated from the n-hexane and ethyl acetate extract of the aerial part of the plant. Bergapten and nodakenetin were isolated from the methanolic extract of the roots. Conclusion: Pituranthos chloranthus contains bergapten, isoimperatorin, nodakenetin, osthol and oxypeucedanin which may be responsible for various pharmacological activities of the plant.

Key words: Apiaceae, Bioactive compounds, oxypeucedanin, Pituranthos chloranthus.

SUMMARY

• First detection of coumarin derivatives from roots and aerial parts of Pituranthos Chloranthus.

• This plant contains osthol and oxypeucedanin that were never reported in the genus Pituranthos.

INTRODUCTION

Medicinal and aromatic plants are the principal health care resources for the majority of people all over the world due to their therapeutic potential. According to the World Health Organization, more than 80% of the world’s population relies on traditional medicine for their primary healthcare needs. The medicinal value of these plants is due to bioactive phytochemical constituent’s action in the human body. Some of the most important bioactive compounds include alkaloids, flavonoids, essential oils, tannins, coumarins and saponins. Consequently, there is growing scientific interest focused on the recovery of bioactive secondary metabolites from natural sources due to their beneficial effects on human health.

These compounds can provide unlimited opportunities for new drug discoveries because of the unmatched availability of chemical diversity. The genus Pituranthos (family Apiaceae) includes more than 20 species. Several species of this genus have been used in traditional medicine for the treatment of fevers, hepatitis, asthma, rheumatism, diabetes and digestive difficulties. Among them, P. chloranthus, commonly known in Arabic as ‘Aljen’, is a small aromatic plant which grows spontaneously in North Africa and is widespread in central and southern Tunisia. Previous phytochemical investigations report the isolation of flavonoids and glycosides from the aerial parts of P. chloranthus such as,isorhamnetin 3-O-β-glucoside, isorhamnetin 3-O-(6''-O-6-rhamnosyl)-β-glucoside, tamarixetin 3-O-β-glucoside, apigenin 6,8-di-C-β-glucoside, luteolin 7-O-(6-rhamnosyl)-3-O-β-glucoside and luteolin 7-O-(3''-O-3-rhamnosyl)-3-O-β-glucoside. In addition, the isolation of β-Sitosterol from the chloroform extract of the aerial parts of this plant has been described. However, other phytochemical studies on the genus Pituranthos have shown the presence of coumarin and furanocoumarin. To the best of our knowledge, P. chloranthus has not been investigated for its coumarin derivatives until now. Therefore, we report here, for the first time, the isolation and the characterization of some coumarin derivatives from the extract of the roots and aerial parts of this plant growing wild in Tunisia.
MATERIALS AND METHODS

Plant material
Different samples of *P. chloranthus* (Coss. and Dur.) (Apiaceae) were collected at the flowering stage in February 2014 from Naffatia region located in southeastern Tunisia.

Samples were authenticated by use of *Flore de la Tunisie*.12 After the collection, the fresh vegetable matter was dried in the shade, and the aerial parts were then separated from the roots.

Extraction and isolation of aerial parts

The dried and powdered aerial parts of *P. chloranthus* were extracted successively in *n*-hexane, ethyl acetate and ethanol, using the maceration method at room temperature. After 48 hours, the different extracts were filtered and concentrated in *vacuo* to give the corresponding extract. The *n*-hexane and ethyl acetate soluble fractions (4 g) were dissolved in a minimum volume of ethyl acetate and adsorbed into silica gel (Merck, 60-120 mesh). After evaporation of the solvent, each resulting mass was subjected to silica gel column chromatography (CC). The *n*-hexane and ethyl acetate columns were then eluted with different solvents using increasing polarity starting from petroleum ether (100%) and ending with ethyl acetate (100%) to yield respectively 681 and 405 fractions collected on the basis of their TLC profiles. Compound (1) was isolated from the *n*-hexane fractions 144-158 (20% of ethyl acetate and 80% of petroleum ether) and crystallized as a pure compound. The second compound (Compound 2) was also isolated from *n*-hexane fractions 205-210 (30% of ethyl acetate and 70% of petroleum ether).

This fraction was further chromatographed over silica gel column using petroleum ether and ethyl acetate in different ratios to get 60 subfractions. The subfractions 33-45 (10% of ethyl acetate with 90% of petroleum ether) were mixed and recrystallized to obtain Compound (2).

Compound (3) was isolated from ethyl acetate fractions 240-253 (40% of ethyl acetate and 60% of petroleum ether). This fraction was subjected to silica gel column chromatography to yield 45 subfractions in which the subfractions 28-45 afford Compound (3).

Extraction and isolation of roots

Dried and powdered roots of *P. chloranthus* were extracted with methanol using a speed extractor apparatus at 200°C and evaporated using a Rotavapor apparatus at 40°C. The concentrated crude methanol extract obtained after evaporation of the solvent was subjected to silica gel chro

<FIGURE 2: CHEMICAL STRUCTURE OF OSTHOL>
assignable to H-9 and H-10, respectively (Figure 7). The presence of a singlet proton at δ_H 7.16 ppm can be attributed to the proton attached to carbon atom number 13. The signal 17, which appears at δ_H 5.54 ppm can be assigned to the olefinic proton attached to carbon atom 17. In addition, the spectrum showed a proton doublet at δ_H 4.93 ppm attributed the oxymethylene proton. The signals 19 (singlet) and 20 (singlet), appearing respectively at 1.80 ppm and 1.70 ppm, are due to the isopentenyl group protons attached to carbon atoms 19 and 20. These attributions were confirmed by 13CNMR spectrum and DEPT 135 which displayed a total of 16 atoms of carbon confirming the structure of this compound. The NMR data of this compound was compared favorably to isoimperatorin (1) published in the literature with a molecular formula of C_{16}H_{15}O_{4}. In addition, a survey of the literature showed that this compound has been isolated from the shoots and the roots of Pituranthos triradiatus. However, this is the first time that this compound was isolated from P. Chloranthus.

Compound (2)
This compound was obtained as white crystal. The HR-MS showed a molecular ion peak at m/z 245.1167 [M+H]+ in agreement with the proposed structure of the known prenylated coumarin, osthole, with the molecular formula C_{15}H_{16}O_{3} (Figure 8). The 'H NMR spectrum of this compound showed two proton doublets at δ_H 6.24 (J=9.5 Hz) and 6.82 (J=8 Hz), characteristic of the H-3 and H-6 of the isolated compound (Figure 9). The presence of further two proton doublets at δ_H 7.3 (J=8 Hz) and 7.6 (J=9.5 Hz) indicated the presence of H-4 and H-3 in the ring of coumarin. The 'H NMR spectrum also displayed a proton singlet at δ_H 3.92 ppm (s) characteristic of a methoxy group (H6') and a multiplet appeared at δ_H 5.24 ppm (J=7.3 Hz) which can be assigned to the olefine proton attached to carbon atom 2'. In the 'H NMR spectrum, a doublet at 3.54 ppm (J=7.3 Hz) can be attributed to the proton attached to carbon atom 1'. However, the singlets that appear at 1.84 ppm and 1.66 ppm are
due to the isopentenyl group protons attached to carbon atoms 4' and 5', respectively. All these NMR data and those of the literature led to identifying Compound (2) as Osthol with a molecular formula of C_{15}H_{16}O_{3}, which was isolated, for the first time from the Pituranthos genus.

Compound (3)

Compound (3) was obtained as a white powder. The HR-MS gave a molecular ion peak at m/z 287.0923, corresponding to a molecular formula C_{16}H_{14}O_{6} (Figure 10). The ^1H-NMR spectrum shows two AB systems at 8.20, 6.34 ppm (H, d, J = 9.8 Hz, H-5, H-4, respectively) and at 7.61, 6.95 ppm (H each, d, J = 2.2 Hz, H-10, H-9), which are characteristic of the furanocoumarin skeleton (Figure 11). The signal 13, appearing at 7.20 ppm, can be attributed to the methine proton attached to carbon atom 13. The signals H16' (δ_H 4.42) and H16'' (δ_H 4.62) arising from the methylene protons have almost the same chemical shift values of 4.46–4.42 ppm (doublet) and 4.62–4.58 ppm (doublet), respectively. In fact, these protons have the same direct atomic neighbors or a similar chemical environment of methylene group 16.

Signal 17, which appears at 3.24 ppm, can be assigned to the proton attached to carbon atom 17. The signals 20 (singlet) and 21 (singlet) that appear at 1.41 ppm and 1.33 ppm are due to the methyl group protons attached to carbon atoms 20 and 21, respectively. These attributions were confirmed in the DEPT 135 and ^13C-NMR spectrum which displayed a total of 16 carbon resonances. It showed eleven carbon resonances for the furanocoumarin nucleus, as described for oxypeucedanin, and five
GEFFROY-RODIER et al.: Structure of coumarins from Pituranthos Chloranthus

additional signals arising from carbons at the sidechain that accounted for: 2 methyl groups (δC 19.15 and 24.73), one oxymethylene (δC 72.45), one oxymethine (δC 61.23) and a quaternary oxygenated carbon (58.48 ppm). In the HMBC spectrum, the oxymethylene proton signals H16' (δH 4.42) and H16'' (δH 4.62) correlated with the proton signal at δH 6.96 (H-9). Consequently the oxymethylene was in the same side of H9 which was connected to C-9. These data confirmed the structure of (3) as oxypeucedanin with a molecular formula of C16H14O6.

To the best of our knowledge, this compound has been isolated for the first time from the Pituranthos genus.

Compound (4) was obtained as white needle-like crystals. The 13C-NMR spectrum exhibited 12 carbon resonances including five methines, one methoxy, one carbonyl and five quaternary carbons. The 1H-NMR spectrum showed two proton doublets at δH 6.28 (J=9.6 Hz) and δH 8.16 (J=9.6 Hz), characteristic of α-pyrone protons assignable to H-3 and H-4 respectively, and a pair of doublets occurring at δH 7.03 (J=2.2 Hz) and δH 7.61 (J=2.2 Hz), typical of furanic protons assignable to H-8' and H-9 respectively (Figure 12). The spectrum further showed a proton singlet at δH 7.37 and a methoxy signal at δH 4.42, assignable to C-15 of the fu-

**Figure 13:** $^1$H NMR spectrum of compound (5)
ranocoumarin structure. Compared to the published data, the structure of (4) was identified as bergapten\textsuperscript{19} with a molecular formula of C\textsubscript{17}H\textsubscript{16}O\textsubscript{3}. This compound has been isolated for the first time from \textit{Pituranthos chloranthus}.

\textbf{Compound (5)}

Compound (5) was isolated as colorless plates. HR-MS showed a quasi-molecular ion peak at m/z 247 [M+H]\textsuperscript{+} in accordance with the molecular formula C\textsubscript{23}H\textsubscript{23}O\textsubscript{6}. The \textsuperscript{13}C-NMR spectrum exhibited 14 carbon resonances including two methyl, one methylene, five methines, one carbonyl and five quaternary carbons. The \textsuperscript{1}H NMR spectrum exhibited two doublets at δ\textsubscript{H} 6.21 and 7.62 characteristic to the two olefinic protons of the coumarin moiety (H4 and H5 respectively). Two aromatic protons appeared as a doublet at δ\textsubscript{H} 6.75 and 7.24, assignable to H7 and H13 respectively, and a one-proton triplet at δ\textsubscript{H} 4.74 was assigned to the methine proton coupled to the adjacent methylene group which itself appeared as a doublet at δ\textsubscript{H} 3.24 (Figure 13). Two uncoupled methyl groups resonated as two singulets at δ\textsubscript{H} 1.26 and 1.39.

Therefore, according to these findings and compared to previously reported data,\textsuperscript{20} compound (5) was identified as nodakenetin which was isolated for the first time from \textit{Pituranthos chloranthus}.

\textbf{CONCLUSION}

In conclusion, five compounds (bergapten, isoimperatorin, nodakenetin, osthol and oxypeucedanin) were isolated from the aerial parts and the rhizomes of \textit{P. chloranthus}. Among them, osthol and oxypeucedanin are reported for the first time from the genus \textit{Pituranthos}. However, the literature review revealed that osthol has many biological activities, including the prevention of atherosclerosis and the suppression of hepatic lipids,\textsuperscript{21} as well as antitumor\textsuperscript{22} and anti-inflammatory activities.\textsuperscript{23} As this is the first attempt of any phytochemical investigation from \textit{P. chloranthus} further isolation and purification of other fractions of this plant is recommended, which could yield some novel and bioactive compounds.

\textbf{ACKNOWLEDGEMENTS}

We gratefully acknowledge the Ministry of Higher Education, Scientific Research and Technology in Tunisia for their financial support. We are also very grateful to the Pole Analyse de Molecules Organique, Université de Poitiers for recording HR-MS spectra of the compounds and we also thank Dr. Bruno Violette for NMR spectra. Our thanks also go to Dr. Elena Sasu for proof reading and linguistic support.

\textbf{CONFLICT OF INTEREST}

The authors declare no conflict of interest.
