ABSTRACT
Introduction: Terminalia ferdinandiana Exell. is an endemic Australian plant which is known for its exceptionally high antioxidant content. The fruit is a nutritional food and the leaves and kinos were used in Australian Aboriginal medicine to treat a variety of diseases. However, T. ferdinandiana kinos remain largely unexamined for their medicinal properties. Methods: Solvent extracts were prepared from T. ferdinandiana kinos and their antiproliferative activities against G. duodenalis and were determined by direct enumeration. The anti-proliferative activities against HeLa and Caco2 cancer cell lines were determined using an MTS based cell assay. Toxicity was determined using the Artemia franciscana nauplii bioassay. Results: Methanolic and aqueous T. ferdinandiana kino extracts were strong inhibitors of Caco2 and HeLa cell proliferation, with IC50 values substantially below 1000 µg/mL. In contrast, the mid to lower polarity solvent extractions (ethyl acetate, chloroform and hexane) were less potent inhibitors of cell proliferation. The aqueous and methanolic extracts were also effective inhibitors of G. duodenalis proliferation, albeit with slightly higher IC50 values than against the Caco2 and HeLa cells. All T. ferdinandiana kino extracts were nontoxic in the Artemia franciscana bioassay, with LC50 values substantially >1000 µg/mL. Conclusion: The antiproliferative activity of the T. ferdinandiana kino extracts against G. duodenalis and the HeLa and Caco2 cancer cell lines indicates their potential in the treatment and prevention of giardiasis and some cancers.

Key words: Kakadu plum, Combretaceae, Giardia duodenalis, Anticancer activity, Antiproliferative activity, Caco2, HeLa, Apoptosis.

INTRODUCTION

Plants of the genus Terminalia (family Combretaceae) are amongst the most widely used plants globally for traditional medicine purposes. Many species have antibacterial, antifungal, antiprotozoal, antiviral, antiinflammatory, analgesic, antimalarial, antioxidant, anti-inflammatory and anticancer activities. Some species also have wound healing and cardiovascular effects. Terminalia spp. are characterised by their high antioxidant contents, which may contribute to their therapeutic properties. Several individual species (and traditional medicine combinations containing Terminalia spp.) have been reported to have potent anticancer properties. The Ayurvedic medicine Triphala (which contains Terminalia bellirica (Gawrtn.) Roxb. And Terminalia chebula (Retz.) Lyons) has cytotoxic effects against thymic lymphoma cells, human breast cancer cell lines, human prostate cancer cell lines and human pancreatic cancer cell lines. Conversely, the cytotoxic effects of Triphala are negligible in normal cell lines. T. bellirica extracts have also demonstrated growth inhibitory effects towards human A549 lung cancer cell lines and HepG2 hepatocarcinoma cell lines without the presence of the other plant components present in Triphala. T. bellirica extracts also have synergistic effects with conventional anticancer chemotherapeutics, enhancing the cytotoxic activity of cisplatin and doxorubicin towards the cancer cell lines, indicating their potential as synergistic cancer chemotherapeutic agents.

The Australian species Terminalia ferdinandiana Exell. also has antiproliferative activity against a panel of cancer cell lines. T. ferdinandiana fruit extracts activate caspase-7, caspase-9 and poly (ADP-ribose) polymerase (PARP), indicating that apoptosis induction is via an intrinsic pathway. Extracts prepared from the leaves of two other Australian Terminalia spp. (T. carpentariae and T. grandiflora) were also recently reported to be good inhibitors of Caco2 and HeLa cell proliferation. This study identified 3 lanostane and 2 pentacyclic triterpenoids in the extracts and postulated that they may contribute to this activity.

What all of the studies testing T. ferdinandiana extracts for anticancer activity have in common is that they focus on extracts produced from the fruit. This is perhaps understandable given the extremely high antioxidant capacities of T. ferdinandiana fruit and the reported correlation between antioxidant activity and antiproliferative properties in cancer cell lines. However, there is no record of the fruit of this species being used medicinally. Instead, the first Australians recognised their nutritional value and used the fruit as a food. In contrast, the therapeutic properties of the leaves and kinos were well known to the first Australians. Despite this, there is a lack of studies testing the leaves or kinos for their therapeutic properties. Several recent papers have reported on the antibacterial and anticancer properties of the leaves of this species and have shown that these extracts often have more potent therapeutic properties than extracts prepared from the fruit. However, there is a lack of studies on the medicinal properties of T. ferdinandiana kino extracts. Furthermore, we were unable to find any studies examining the anti-Giardial properties of extracts of either the leaves or kinos, despite reports of potent activity for fruit extracts.
MATERIALS AND METHODS

Plant source and extraction

The Terminalia ferdinandiana Exell. kinos used in this study were supplied and verified by David Boehme of Wild Harvest, Northern Territory (Australia) and were collected from a single tree near Humphy Doo, Australia. Voucher specimens are stored in the School of Natural Sciences, Griffith University, Australia (GUTFK1-2016-1A). The kinos were thoroughly dried using a Sunbeam food dehydrator and stored at -30°C until required. Prior to use, the dried kinos were ground into a coarse powder using a coffee grinder. Individual 1g quantities of the powdered T. ferdinandiana kinos were weighed into separate tubes and 50 mL of methanol, sterile deionised water, ethyl acetate, chloroform or hexane were added. All solvents were obtained from Ajax Chemicals, Australia and were AR grade. The ground T. ferdinandiana kinos were extracted in each solvent for 24 h at 4°C with gentle shaking. The extracts were subsequently filtered through Whatman No. 54 filter paper under vacuum. The solvent extracts were air dried at room temperature. The aqueous extracts were lyophilised by freeze drying at -50°C. The resultant dried extracts were weighed to determine the extraction yield, and dissolved in 10 mL deionised water (containing 1% DMSO) and stored at 4°C until use.

Qualitative phytochemical studies

Phytochemical analysis of the extracts for the presence of saponins, phenolic compounds, flavonoids, phytosterols, triterpenoids, cardiac glycosides, anthraquinones, tannins and alkaloids were conducted by standard assays.\(^{17-19}\)

Inhibitory bioactivity against *Giardia duodenalis* trophozoites

Parasite culture

The *Giardia duodenalis* S-2 (sheep strain 2) trophozoite strain used in this study was a gift from Professor Andre Buret, University of Calgary, Canada. The trophozoites were maintained and subcultured anaerobically at 37°C in TYI-S-33 growth media supplemented with 1% bovine bile (Sigma), 10 % Serum Supreme (Cambrex Bio products) and 200 IU/mL penicillin/200 µg/mL streptomycin (Invitrogen, USA). Confluent mid log phase cultures were passaged every 2 days by chilling the cultures on ice for a minimum of 10 min, followed by vortexing to dislodge the adherent trophozoites from the walls of the culture vessel. Fresh culture media (5 mL) was seeded with approximately 1 x 10^4 trophozoites for each passage.

Evaluation of anti-Giardial activity

Anti-Giardial activity was tested using standard assays.\(^{16,20,21}\) Briefly, 70 µL trophozoite suspension (containing approximately 1 x 10^5 trophozoites) was dispensed into the wells of a 96 well plate. A volume of 30 µL of the test extracts or the vehicle solvent or culture media (for the negative control) were added to individual wells and the plates were incubated anaerobically at 37°C for 12 h in a humidified anaerobic atmosphere. The cell number was determined by direct enumeration and expressed as a % of the untreated control proliferation. All tests were performed in at least triplicate and triplicate controls were included on each plate.

Screen for anticancer bioactivity

Cancer cell lines

The Caco2 and HeLa carcinoma cell lines used in this study were obtained from American Type Culture Collection (Rockville, USA). The cells were cultured in Roswell Park Memorial Institute (RPMI) 1640 medium (Life Technologies), supplemented with 20 mM HEPES, 10 mM sodium bicarbonate, 50 µg/mL streptomycin, 50 IU/mL penicillin, 2 mM glutamine and 10 % foetal calf serum (Life Technologies). The cells were maintained as monolayers in 75 mL flasks at 37°C, 5 % CO2 in a humidified atmosphere until approximately 80 % confluent.

Evaluation of cancer cell antiproliferative activity

The antiproliferative activity of the extracts was assessed as previously described.\(^{6,12}\) Aliquots of resuspended Caco2 or HeLa cells (70 µL, containing approximately 5000 cells) and 30 µL of the test extracts or cell media (for the negative control) were added to individual wells of a 96 well plate and incubated at 37°C, 5 % CO2 for 12 hours in a humidified atmosphere. A volume of 20 µL of Cell Titer 96 Aqueous One solution (Promega) was subsequently added to each well and the plates were incubated for a further 3 h. Absorbances were recorded at 490 nm using a Molecular Devices, Spectra Max M3 plate reader. All tests were performed in at least triplicate and triplicate controls were included on each plate. The antiproliferative activity of each test was calculated as a percentage of the negative control using the following formula:

\[
Proliferation (% \text{untreated control}) = \left( \frac{A_t}{A_{nc}} \right) \times 100
\]

\(A_t\) is the corrected absorbance for the test extract (calculated by subtracting the absorbance of the test extract in media without cells from the extract cell test combination) and \(A_{nc}\) is the corrected untreated control (calculated by subtracting the absorbance of the untreated control in media without cells from the untreated control media combination).

Toxicity screening

Reference toxin for toxicity screening

Potassium dichromate (K2Cr2O7) (AR grade, Chem-Supply, Australia) was prepared as a 1.6 mg/mL solution in distilled water and was serially diluted in artificial seawater for use in the *Artemia franciscana* nauplii bioassay.

*Artemia franciscana* nauplii toxicity screening

Toxicity was tested using a modified *Artemia franciscana* nauplii lethality assay as previously described.\(^{22-23}\) Briefly, *A. franciscana* nauplii were exposed to diluted plant extracts or the reference toxin and incubated at 25 ± 1°C under artificial light (1000 Lux). The wells were checked after 24 h exposure and the % mortality per well was calculated. The LC50 with 95% confidence limits for each treatment was calculated using probit analysis.

Statistical analysis

Data are expressed as the mean ± SEM of at least three independent experiments. One-way ANOVA was used to calculate statistical significance between control and treated groups with a \(P\) value < 0.01 considered to be statistically significant.

RESULTS

Liquid extraction yields and qualitative phytochemical screening

Extraction of 1 g of the dried and powdered *T. ferdinandiana* kinos with solvents of varying polarity yielded dried plant extracts ranging from 486 mg (ethyl acetate extract) to 784 mg (methanol extract) (Table 1). The dried extracts were resuspended in 10 mL of deionised water (containing 1% DMSO) resulting in the extract concentrations shown in Table 1. Qualitative phytochemical studies (Table 1) determined that methanol and water extracted the widest range of phytochemicals. Both contained moderate to high levels of phenolic (both water soluble and insoluble phenolic), triterpenoids, flavonoids and tannins, as well as low...
levels of saponins. The ethyl acetate extract contained only moderate levels of phenolic and tannins, as well as low levels of flavonoids. Only low levels of flavonoids and tannins were detected in the chloroform and hexane extracts. Phytosterols, alkaloids, cardiac glycosides and anthraquinones were not detected in any extract.

**Inhibition of* Giardia duodenalis* proliferation**

*T. ferdinandiana* kino extracts were screened for their ability to inhibit *G. duodenalis* growth (Figure 1). The methanol, water, ethyl acetate and chloroform extracts displayed significant inhibitory activity (p<0.01). The methanol and water extracts were particularly potent, completely inhibiting Giardial growth. The ethyl acetate and chloroform extracts were also effective at inhibiting trophozoite growth, albeit to a lesser extent (by ≤ 25 % compared to the growth of the negative controls). The hexane extract was completely ineffective against *G. duodenalis* proliferation, with no significant difference to the untreated control levels.

The *T. ferdinandiana* kino extracts were further tested over a range of concentrations to determine the IC$_{50}$ values (Table 2) for each extract against *G. duodenalis*. Inhibition of trophozoite growth was dose-dependent, with the level of inhibitory activity decreasing at lower concentrations. The methanolic and aqueous extracts were good inhibitors of *G. duodenalis* proliferation, with IC$_{50}$ values of 996 and 1175 µg/mL respectively.

**Inhibition of cancer cell proliferation**

Aliquots of all extracts were tested for the ability to block the proliferation of Caco2 (Figure 2) and HeLa (Figure 3) cell lines. All of the *T. ferdinandiana* kino extracts displayed significant (p<0.01) antiproliferative effects against Caco2 cells (Figure 2). Indeed, all extracts inhibited Caco2 cell proliferation by ≥85%, compared to the untreated control. This inhibition was particularly noteworthy and was substantially better than the cisplatin control (50 µg/mL), which inhibited Caco2 proliferation by <75%. The extracts were similarly effective at inhibiting HeLa cancer cell

**Table 1:** The mass of dried extracted material, the concentration after resuspension in deionised water (containing 1% DMSO) and qualitative phytochemical screenings of the *T. ferdinandiana* kino extracts.

proliferation (Figure 3), although the mid to lower polarity ethyl acetate, chloroform and hexane extracts were less potent inhibitors of HeLa cell proliferation compared to Caco2 proliferation (judged by the % proliferation inhibition).

The antiproliferative efficacy of the *T. ferdinandiana* kino extracts was further quantified by determining the IC$_{50}$ values for each extract which inhibited cell proliferation against each cell line (Table 2). The aqueous and methanolic extracts were particularly effective at inhibiting cancer cell proliferation, with IC$_{50}$ values substantially $<$1000 µg/mL against both Caco2 and HeLa cell lines. The aqueous extract was the most potent inhibitor of Caco2 and HeLa proliferation, with IC$_{50}$ values of 275 and 259 µg/mL respectively.

**Quantification of toxicity**

All extracts were initially screened at 2000 µg/mL in the *Artemia* nauplii bioassay following 24 h exposure (Figure 4). For comparison, the reference toxin potassium dichromate (1000 µg/mL) was also tested. The potassium dichromate reference toxin was rapid in its onset of mortality, inducing mortality within the first 3 h of exposure and 100 % mortality was evident following 4-5 h (unpublished results). Similarly, the methanolic and aqueous *T. ferdinandiana* kino extracts displayed 100 % mortality rates at 24h and were thus deemed to be toxic. All other extracts induced levels of mortality which were below 50% and were thus deemed to be

Numbers indicate the mean IC$_{50}$ or LC$_{50}$ values of triplicate determinations.

- indicates that inhibition was not evident at any dose tested. CND indicates that IC$_{50}$ or LC$_{50}$ values could not be obtained as the % inhibition or % mortality did not exceed 50 % at any dose tested.
nontoxic.

To further quantify the effect of toxin concentration on the induction of mortality, the extracts were serially diluted in artificial seawater to test across a range of concentrations in the Artemia nauplii bioassay. Table 2 shows the LC50 values of the extracts towards A. franciscana. No LC50 values are reported for the ethyl acetate, chloroform or hexane T. ferdinandiana kino extracts as less than 50% mortality was seen for all concentrations tested. Extracts with LC50 values >1000 µg/mL towards Artemia nauplii have been defined as being nontoxic.4 As LC50 values >1000 µg/mL were determined for the methanolic and aqueous extracts, they were also deemed to be nontoxic.

**DISCUSSION**

*T. ferdinandiana* fruit is a highly nutritious food and the leaves and kinos have been used as traditional Australian Aboriginal medicines for thousands of years.12 Due to its extremely high antioxidant content,15 most studies into the therapeutic properties of *T. ferdinandiana* have focused on fruit extracts. Several studies have reported potent antibacterial properties for fruit solvent extracts against food spoilage fungi17 and food poisoning bacteria,18,19 as well against the bacterial triggers of rheumatoid arthritis13 and multiple sclerosis.20 It has also been reported to be a potent growth inhibitor of the endospore forming pathogens Bacillus anthracis21 and Clostridium perfringens.28 Several studies have also tested extracts prepared from *T. ferdinandiana* leaves on similar bacterial species and report higher potency compared to the equivalent fruit extracts.13,27,28,29 Exports produced from the fruit are also potent inhibitors of the proliferation of the gastrointestinal protozoal parasite, Giardia duodenalis.14 However, we were unable to find any studies that tested leaf or kino extracts against *G. duodenalis*, or other protozoal parasites. Several studies have also reported that *T. ferdinandiana* fruit extracts have anti-proliferative activity against several cancer cell lines.7,8 These studies reported that the *T. ferdinandiana* fruit extracts blocked proliferation via apoptosis induction.4 Interestingly, one of these studies also tested leaf extracts and reported similar activity but stronger potency compared to the fruit extract.7 Despite the previous studies examining the therapeutic properties of other parts of the plant and their use in traditional medicine, *T. ferdinandiana* kinos remain to be evaluated for their therapeutic properties.

The current study examined the anti-proliferative properties of *T. ferdinandiana* kinos extracts against the food/water borne gastrointestinal parasite *G. duodenalis*, and against two cancer cell lines. Potent growth inhibition of *G. duodenalis* was noted for the kinos extracts. Giardial infection (giardiasis) is a re-emerging disease which affects large numbers of individuals worldwide, with higher incidence in countries with poorer socio-economic conditions, inadequate sanitary conditions, untreated water supplies and poor diet.28 Whilst generally not fatal, giardiasis results in debilitating symptoms including bloating, diarrhoea, excess gas, loss of appetite, loose and watery stool, stomach cramps and haematuria. Currently, there are only a narrow range of drugs effective against giardiasis, including quinolones and imidazole derivatives. None of these drugs is ideal as they produce unpleasant side effects including nausea, vertigo, vomiting, diarrhoea and hallucinations.30,31 Furthermore, recent reports of the failure of current treatments to address this disease indicate a developing drug resistance of several *Giardia* strains.25 Recent studies have highlighted the potential of plant medicines and have demonstrated that some plant components are very effective inhibitors of *Giardia duodenalis* growth, with similar potency to the gold standard drug metronidazole 16,26. Our studies demonstrate that *T. ferdinandiana* kino extracts also possess anti-Giardial activity. Whilst, further studies are required to identify the active component(s), previous studies have identified several tannins and lactone compounds in extracts produced from the leaves of this species. Notably, all these compounds have inhibitory activity against amoebic protozoans.16 It is possible that these compounds may also contribute to the anti-Giardial activity seen in our study, although further tests are required to determine if they are present in the kinos extracts.

The antiproliferative efficacy of the *T. ferdinandiana* kinos extracts was also examined against two human cancer cell lines in vitro: Caco2 (colorectal) and HeLa (cervical). Anti-proliferative activity was evident for all the *T. ferdinandiana* kinos extracts, although it was particularly noteworthy for the methanol and water extracts, with IC50 values substantially <1000 µg/mL. The aqueous extract was a particularly potent inhibitor of Caco2 and HeLa proliferation, with IC50 values of approximately 275 and 260 µg/mL respectively. These findings support and extend previous studies examining the anticancer effects of *T. ferdinandiana* fruit7,8 and leaf extracts7 against these and other cell lines. The earlier studies also examined the antiproliferative mechanism and determined that the extracts induced apoptosis.7,8 Furthermore, as the fruit extracts activate caspase-7, caspase-9 and poly (ADP-ribose) polymerase (PARP), it is likely that apoptosis induction is via an intrinsic pathway.1 Our study did not examine the antiproliferative mechanism of the *T. ferdinandiana* kinos extracts. Nor did we identify the active components of the cytotoxic extracts. Further isolation and identification studies are required to determine these details.

The findings reported here also demonstrate that all *T. ferdinandiana* kinos extracts were nontoxic towards *A. franciscana* nauplii. Extracts with LC50-values >1000 µg/mL towards *Artemia* nauplii have been defined as being nontoxic.21 However, further studies using normal human cell lines are required to verify the safety of these extracts for therapeutic use. Furthermore, bioactivity driven separation studies are required to isolate the active components and determine their mechanism of action. The results of this study indicate that the *T. ferdinandiana* kinos extracts examined in this report are worthy of further study due to their anti-Giardial activity and ability to block cancer Caco2 and HeLa carcinoma cell proliferation. Further evaluation of the anti-Giardial and anticancer properties of these extracts is warranted. Likewise, bioactivity driven purification studies are needed to examine the mechanisms of action of these agents.

**CONCLUSION**

The potent antiproliferative activity and lack of toxicity of the methanolic and aqueous *T. ferdinandiana* kinos extracts indicates their potential in the treatment and prevention of giardiasis and some cancers. Purification and identification of the bioactive components is needed to examine the mechanisms of action of these agents.

**ACKNOWLEDGEMENT**

The authors are grateful to David Boehme of Wild Harvest, Northern Territory, Australia for providing the *T. ferdinandiana* kinos used in these studies. We are also thankful to Professor Andre Buret, University of Calgary, Canada for the gift of the *G. duodenalis* S-2 (sheep strain 2) trophozoite strain used in this. Financial support for this work was provided by the Environmental Futures Research Institute, Griffith University.

HIGHLIGHTS OF PAPER

- The aqueous and methanolic extracts were also effective inhibitors of cell proliferation.
- The mid to lower polarity solvent extractions were less potent inhibitors of cell proliferation.
- Non-toxic extracts were non-toxic in the nauplii assay.

PICTORIAL ABSTRACT

- Methanolic and aqueous T. Ferdinandiana kino extracts were strong inhibitors of Caco2 and HeLa cell proliferation.
- The aqueous extract was particularly potent against Caco2 and HeLa cells (IC50 ~ 275 and 260 µg/mL respectively).
- The mid to lower polarity solvent extractions were less potent inhibitors of cell proliferation.
- Growth inhibitory activity of Kakadu plum extracts against the opportunistic pathogen Clostridium perfringens.
- Growth inhibitory activity of Kakadu plum extracts against the opportunistic pathogen Clostridium perfringens.
- The aqueous and methanolic extracts were also effective inhibitors of G. duodenalis proliferation (IC50 values of 1000 and 1200 µg/mL respectively).
- All extracts were non-toxic in the Artemia nauplii assay.

ABOUT AUTHORS

Dr. I. E. Cook leads a research team in the Environmental Futures Research Institute and the School of Natural Sciences at Griffith University, Australia. His research involves bioactivity and phytochemical studies into a variety of plant species of both Australian and international origin, including Aloe vera, South Asian and South American tropical fruits, as well as Australia plants including Scaevola spinescens, Pittosporum phylliraeoides, Terminalia Ferdinandi (Kakadu plum), Australian Acacias, Syzygiums, Pentalostigmans and Xanthorrhoea johnsonii (grass trees). This range of projects has resulted in nearly 200 publications in a variety of peer reviewed journals.
